Received 12 June 1984

This paper presents a new model and branch-and-bound algorithm for the asymmetric m -travelling salesmen problem. The algorithm uses a Lagrangean relaxation, a subgradient algorithm to solve the Lagrangean dual, a greedy algorithm for obtaining minimal m -trees, penalties to strengthen the lower bounds on candidate problems, and a new concept known as staged optimization. Computational experience for problems having up to 100 cities is presented.

1. Overview

This paper extends the highly successful algorithm of Held and Karp [12, 13] for the travelling salesman problem, to the asymmetric m -travelling salesmen problem. The algorithm involves the use of a Lagrangean dual within a branch-and-bound structure. A subgradient procedure is used to solve the dual and it is shown that a greedy algorithm may be used to evaluate points of the dual function.

We now formally state the *asymmetric m -travelling salesmen problem*. We define a *directed tour* beginning at city n as a sequence of distinct cities $\{n, i_1, i_2, \dots, i_l\}$ where $l \geq 1$. Given n cities $(1, \dots, n)$ and m salesmen, all based at city n , we wish to find a set of m directed tours such that each city other than n is a member of exactly one directed tour. Let c_{ij} denote the distance from city i to city j and let $c_{ni_1} + c_{i_1 i_2} + \dots + c_{i_{l-1} i_l} + c_{i_l n}$ denote the distance for the directed tour $\{n, i_1, \dots, i_l\}$. The objective is to select m directed tours (one for each salesman) such that the total distance for all tours is a minimum. A related problem has also been discussed in the literature in which the objective is to select at most m directed tours with total minimum distance (see [2]). Clearly, for $m = 1$, both models are the classical asymmetric travelling salesman problem.

This model was first formulated in integer programming terms by Miller, Tucker, and Zemlin [18]. Svetska and Huckfeldt [19] developed a specialized branch-and-

* This research was supported in part by the Air Force Office of Scientific Research under Contract Number AFOSR 77-3151. This work was part of the first author's dissertation.

bound algorithm for this problem which uses a linear programming relaxation. Also, Gavish and Srikanth [7] developed a branch-and-bound algorithm which uses a different relaxation. The Gavish–Srikanth model does not permit the use of a greedy algorithm to solve subproblems; whereas, our model does. Bellmore and Hong [5] proved that this model was equivalent to an asymmetric travelling salesman problem on $n + m - 1$ cities. The question of whether this problem should be attacked directly as in [7, 19] and the present work or whether it should be converted to its one salesman equivalent and solved using [3] and [13] is an open question.

2. The model

In this section, we present a new model for the asymmetric m -travelling salesmen problem. The model is developed using the notion of an m -tree, which is a generalization of the Held–Karp 1-tree. The m -tree is defined such that it has the matroidal property so that the integer programming relaxation is solvable via a greedy algorithm. The original generalization proposed by Held and Karp [12] is not matroidal.

Let the decision variable be

$$x_{ij} = \begin{cases} 1, & \text{if some salesman travels from city } i \text{ to city } j; \\ 0, & \text{otherwise.} \end{cases}$$

Assuming that each salesman is based at city n , we call any directed tour on cities $1, \dots, n-1$ a *directed subtour*. Then the asymmetric m -travelling salesmen problem may be stated mathematically as follows:

$$\min \sum_{i=1}^n \sum_{j=1}^n c_{ij} x_{ij}, \quad (1)$$

$$\text{s.t. } \sum_{k=1}^n x_{kj} = \begin{cases} 1, & \text{for } j = 1, \dots, n-1, \\ m, & \text{for } j = n, \end{cases} \quad (2)$$

$$\sum_{k=1}^n x_{ik} = \begin{cases} 1, & \text{for } i = 1, \dots, n-1, \\ m, & \text{for } i = n, \end{cases} \quad (3)$$

$$\begin{aligned} x_{ij} &= 0 \text{ or } 1 & (\text{all } i, j), \\ x_{ii} &= 0 & (\text{all } i), \end{aligned} \quad (4)$$

$$\text{no directed subtours.} \quad (5)$$

For the classical travelling salesman problem (i.e., $m = 1$), a pair of expository papers by Held and Karp [12, 13] showed that (4) and (5) could be replaced by a constraint that required the graphical structure associated with any feasible vector x to be a 1-tree. A 1-tree is a graphical concept and does not involve direction. If $c_{ij} > c_{ji}$, then the arc (i, j) is never selected to link nodes i and j . A 1-tree on a graph having n nodes (cities) is a spanning tree on $n - 1$ nodes and two distinct edges connecting node n to two other nodes. Letting $Y = \{(x_{11}, \dots, x_{1n}, \dots, x_{n1}, \dots, x_{nn}) : x_{ii} = 0,$

$x_{ij}=0$ or 1 and the edges ij having $x_{ij}=1$ form a 1-tree}, the asymmetric travelling salesman problem may be stated as (1), (2), (3), $x \in Y$, and $m=1$.

We now generalize the notion of a 1-tree to an m -tree.

An m -tree on a graph having n nodes is an acyclic graph having $n-m-1$ edges on $n-1$ nodes and $2m$ edges connecting node n to other nodes.

Note that for an m -tree (i, j) and (j, i) are parallel edges both of which link nodes i and j . For $i, j < n$, only one of these edges may appear in an m -tree. If $i = n$ or $j = n$, then both edges may appear in an m -tree. Also, every m -tree has $n+m-1$ edges and an m -tree need not be connected. A set of 2-trees is illustrated in Fig. 1.

Letting $X = \{(x_{11}, \dots, x_{1n}, \dots, x_{n1}, \dots, x_{nn}) : x_{ii}=0, x_{ij}=0 \text{ or } 1, \text{ and the edges } ij \text{ with } x_{ij}=1 \text{ form an } m\text{-tree}\}$, the m -travelling salesmen problem may be stated as follows:

$$\min \sum_{i,j} c_{ij} x_{ij}, \quad (6)$$

$$\text{s.t. } \sum_k x_{kj} = \begin{cases} 1, & \text{for } j=1, \dots, n-1, \\ m, & \text{for } j=n, \end{cases} \quad (7)$$

$$\sum_k x_{ik} = \begin{cases} 1, & \text{for } i=1, \dots, n-1, \\ m, & \text{for } i=n, \end{cases} \quad (8)$$

$$x \in X. \quad (9)$$

A specialization of (6)–(9) for the symmetric case need have only n constraints in place of (7) and (8) (see Ali [1]).

Fig. 1. Examples of 2-trees on 5 nodes ($n=5, m=2$).

3. The algorithm

In this section we present a branch-and-bound algorithm for the asymmetric m -travelling salesmen problem. The algorithm uses a Lagrangean relaxation, a subgradient algorithm to solve the Lagrangean dual, a greedy algorithm for evaluation of a point of the dual function, penalties to strengthen the lower bounds obtained by the greedy algorithm, and a new concept known as staged optimization. Each of these techniques are explained in the subsections to follow.

3.1. Lagrangean relaxation

The Lagrangean dual of (6)–(9) selected for this algorithm is as follows:

$$\max_{u,v} \Theta(u,v) \quad (10)$$

where

$$\begin{aligned} \Theta(u,v) = \min_{x \in X} \left\{ \sum_{i,j} c_{ij} x_{ij} + \sum_{i=1}^{n-1} u_i \left(\sum_{j=1}^{n-1} x_{ij} - 1 \right) \right. \\ \left. + u_n \left(\sum_{j=1}^n x_{nj} - m \right) + \sum_{j=1}^{n-1} v_j \left(\sum_{i=1}^{n-1} x_{ij} - 1 \right) \right. \\ \left. + v_n \left(\sum_{i=1}^n x_{in} - m \right) \right\}. \end{aligned} \quad (11)$$

After rearranging terms

$$\Theta(u,v) = \min_{x \in X} \left\{ \sum_{i,j} \bar{c}_{ij} x_{ij} \right\} - \alpha$$

where

$$\alpha = \sum_{k=1}^{n-1} (u_k + v_k) - m(u_n + v_n) \quad \text{and} \quad \bar{c}_{ij} = c_{ij} + u_i + v_j.$$

The Lagrangean dual has been used by both Held and Karp [12, 13] and Bazaraa and Goode [3] in their highly successful work on the travelling salesman problem. Our relaxation is a natural extension of their model. Lagrangean relaxation for general integer programs has been extensively studied by Geoffrion [10].

Consider the following results which relate the Lagrangean dual and the primal.

Theorem 1 (Bazaraa and Shetty [4]). *Let x^* solve (6)–(9) and let (u^*, v^*) solve (10), (11). Then*

$$\Theta(u^*, v^*) \leq \sum_{i,j} c_{ij} x_{ij}^*.$$

Theorem 2 (Bazaraa and Shetty [4]). *$\Theta(u, v)$ is concave.*

Theorem 3 (Geoffrion [8]). Let (\bar{u}, \bar{v}) be any vectors, let $\bar{x} \in X$ solve $\Theta(\bar{u}, \bar{v})$ and let

$$r_i = \begin{cases} \sum_j \bar{x}_{ij} - 1, & \text{for } i = 1, \dots, n-1 \\ \sum_j \bar{x}_{ij} - m, & \text{for } i = n \end{cases}$$

$$s_j = \begin{cases} \sum_i \bar{x}_{ij} - 1, & \text{for } j = 1, \dots, n-1 \\ \sum_i \bar{x}_{ij} - m, & \text{for } j = n. \end{cases}$$

The vector (r, s) is a subgradient of $\Theta(u, v)$ at the point (\bar{u}, \bar{v}) .

The above three results are well-known and are easily proved. Given the optimal vectors associated with both the primal and dual, the non-negative quantity

$$\frac{\sum_{i,j} c_{ij} x_{ij}^* - \Theta(u^*, v^*)}{\sum_{i,j} c_{ij} x_{ij}^*} \quad (12)$$

is called the *duality gap*.

For this work, the subgradient algorithm ([14, 16]) is used to solve the dual (10) and (11). Our implementation of this general method is presented below.

ALG-1: Subgradient optimization method for dual

0. Parameter Selection and Initialization

- [Select Step Size Parameters] Select $\bar{G}, \bar{H}, \lambda_1, \dots, \lambda_{\bar{G}}$.
- [Set Initial Solution] $u \leftarrow 0, v \leftarrow 0, u^* \leftarrow 0, v^* \leftarrow 0, r^* \leftarrow 0, s^* \leftarrow 0$.
- [Set Lower Bound] $L \leftarrow -\infty$.
- [Obtain over Estimate] Set $\bar{\Theta}$ such that $\bar{\Theta} \geq \max_{u,v} \Theta(u, v)$.
- [Initialize Counters] $i \leftarrow 1, h \leftarrow 0$.

1. Solve Subproblem

- [Evaluate Dual at (u, v)] Let x^* solve $\min_{x \in X} \{ \sum_{i,j} \bar{c}_{ij} x_{ij} \}$ and set $\Theta \leftarrow \sum_{i,j} \bar{c}_{ij} x_{ij}^* - \alpha$.
- [Determine Subgradient]

$$\text{Set } r_i = \begin{cases} \sum_j \bar{x}_{ij}^* - 1, & \text{for } i = 1, \dots, n-1, \\ \sum_j \bar{x}_{ij}^* - m, & \text{for } i = n, \end{cases}$$

$$s_j = \begin{cases} \sum_i \bar{x}_{ij}^* - 1, & \text{for } j = 1, \dots, n-1, \\ \sum_i \bar{x}_{ij}^* - m, & \text{for } j = n. \end{cases}$$

- [Test for Optimality] If $r = s = 0$, stop with (u, v) an optimum for the dual and x^* an optimum for the primal.
- [Improved Solution?] If $\Theta > L$, then $L \leftarrow \Theta, u^* \leftarrow u, v^* \leftarrow v, r^* \leftarrow r, s^* \leftarrow s$, and go to 2.

- e. [Test Step Size Counter] $h \leftarrow h + 1$. If $h = \bar{H}$, go to 3.
2. *Move to New Point*
 $(u, v) \leftarrow (u, v) + [\lambda_i(\bar{\Theta} - \Theta)/\|(r, s)\|](r, s)$, and go to 1.
3. *Change Step Size or Terminate*
 If $i = \bar{G}$, terminate with (u^*, v^*) as an optimum for the dual; otherwise, $h \leftarrow 0$, $i \leftarrow i + 1$, $(u, v) \leftarrow (u^*, v^*) + \{\lambda_i[\bar{\Theta} - \Theta(u^*, v^*)]/\|(r^*, s^*)\|\}(r^*, s^*)$, and go to 1.

An excellent discussion of convergence results for the subgradient algorithm are given in Helgason [15].

3.2. Matroidal structure of m -trees

To implement ALG-1 efficiently, one needs a fast procedure for solving

$$\min_{x \in X} \left\{ \sum_{i,j} \bar{c}_{ij} x_{ij} \right\}. \quad (13)$$

In this section we show that X has a matroidal structure and (13) may be solved by a greedy algorithm.

We now present results from matroid theory which will be used in the development of an efficient algorithm for (13). Recall that a *matroid*, $M = [Z, \psi]$, is a finite set Z and a set ψ of subsets of Z such that the following axioms hold:

- M1. $\emptyset \in \psi$.
 M2. If $\mathcal{X} \in \psi$ and $\mathcal{Y} \subseteq \mathcal{X}$, then $\mathcal{Y} \in \psi$.
 M3. If $\mathcal{U}, \mathcal{V} \in \psi$ with $|\mathcal{U}| = |\mathcal{V}| + 1$, then there exists an $x \in \mathcal{U} - \mathcal{V}$ such that $\mathcal{V} \cup \{x\} \in \psi$.

Let 2^Z denote the power set of Z . Then the elements of $\psi \subset 2^Z$ are called *independent* subsets of 2^Z and $2^Z - \psi$ are called *dependent* subsets. A maximal independent subset is called a *base*.

We now show that a greedy algorithm can be used to find a minimum weight base. Let $\beta \subset \psi$ denote the set of bases for some matroid. Let $w: Z \rightarrow R$ be a weight function and extend this to $w: 2^Z \rightarrow R$ as follows:

$$w(C) = \sum_{e \in C} w(e), \quad C \subset Z.$$

The minimal weight base problem may be described as follows:

Find $\mathcal{X} \in \beta$ such that

$$w(\mathcal{X}) = \min_{\mathcal{B} \in \beta} w(\mathcal{B}). \quad (14)$$

An optimal base \mathcal{X} may be obtained by employing the following algorithm.

ALG-2: Greedy algorithm for a minimal weight base

0. $\mathcal{X}_0 \leftarrow \emptyset$, $i \leftarrow 1$, $\mathcal{Y} \leftarrow Z$.

1. Find x_i such that $w(x_i) = \min\{w(x) : x \in \mathcal{Y}, \{x\} \cup \mathcal{X}_{i-1} \in \psi\}$. If no such x_i exists, stop, \mathcal{X}_{i-1} is an optimum.
2. $\mathcal{X}_i \leftarrow \mathcal{X}_{i-1} \cup \{x_i\}$, $\mathcal{Y} \leftarrow \mathcal{Y} - \{x_i\}$, $i \leftarrow i+1$ and go to 1.

Edmonds [6] proved that ALG-2 produces an optimum for (14).

To apply Edmonds result to problem (13) we must show that X (the set of m -trees) is the set of bases for some matroid. If this can be shown, then (13) can be solved by the efficient greedy algorithm (ALG-2).

Let $\hat{A} = \{(i, j) : 1 \leq i \leq n-1, i \leq j \leq n-1, i \neq j\}$, $\tilde{A} = \{(i, n), (n, i) : 1 \leq i \leq n-1\}$, and let $A = \hat{A} \cup \tilde{A}$. Then we will call a set $\mathcal{X} \subset \hat{A}$ independent if the edges of \mathcal{X} do not form a cycle. We will call a set $\mathcal{X} \subset \tilde{A}$ independent if $|\mathcal{X}| \leq 2m$. Furthermore, $\mathcal{X} \subset A$ will be called independent if $|X \cap \hat{A}| \leq n+m-1$ and $X \cap \hat{A}$ and $X \cap \tilde{A}$ are independent. Let ψ be the set of all independent subsets of A . Clearly, a maximal independent subset of A is an m -tree. Hence, we need only show that $[A, \psi]$ is a matroid to prove that ALG-2 solves (13).

Before proving that $[A, \psi]$ is a matroid we give the following preliminary result.

Lemma 4 (Glover and Klingman [11]). *Let G be a graph and let Ω be the set of all spanning trees of G . Let $E_1 \subseteq S_1$ and $E_2 \subseteq S_2$ where $S_1, S_2 \in \Omega$ and $|E_1| = m_1$, $|E_2| = m_2$, $m_1 > m_2$. Then there exists an arc $e \in E_1 - E_2$ such that $E_2 \cup \{e\} \subseteq S_3 \in \Omega$.*

Lemma 4 will be used in the proof of the following result.

Theorem 5. $[A, \psi]$ is a matroid.

Proof. Axioms M1 and M2 hold trivially. Therefore, we must show that M3 holds. Let U_1 and $U_2 \in \psi$ with $|U_i| = u_i$, $|U_i \cap \hat{A}| = t_i$, $|U_i \cap \tilde{A}| = s_i$, $i = 1, 2$ and $u_1 = u_2 + 1$. Let $e \in U_1 - U_2$.

Case 1: $s_1 > s_2$. If $s_1 > s_2$, then there exists an arc $e \in [(U_1 \cap \tilde{A}) - U_2]$ for which $U_2 \cup \{e\} \in \psi$.

Case 2: $s_1 \leq s_2$. If $s_1 \leq s_2$, then $t_1 \geq t_2 + 1$. Now $(U_1 \cap \hat{A})$ and $(U_2 \cap \hat{A})$ have no cycles. By Lemma 4, there exists an $e \in (U_1 \cap \hat{A}) - (U_2 \cap \hat{A})$ such that $(U_2 \cap A) \cup \{e\}$ has no cycles. Therefore, $U_2 \cup \{e\} \subset U_3 \in \psi$.

This completes the proof of Theorem 5.

Therefore, the minimal m -tree problem,

$$\min_{x \in X} \left\{ \sum_{i,j} \bar{c}_{ij} x_{ij} \right\},$$

is solvable via ALG-2.

3.3. Separation

In [2] it is shown that the number of feasible solutions for an n city asymmetric m -travelling salesmen problem having m salesmen is

$$\binom{n-1}{m} \frac{(n-2)!}{(m-1)!}. \quad (15)$$

The proof of this result is constructive and shows precisely how one may generate an enumeration tree for this problem.

The tree is generated in two phases with phase 1 corresponding to $\binom{n-1}{m}$ in (15) and phase 2 corresponding to $(n-2)!/(m-1)!$. Assume that the tree is constructed from top down and let the single top node correspond to level 0. All nodes at level l in the enumeration tree will have l arcs fixed and the tree has $n-1$ levels since fixing $n-1$ arcs via the prescribed procedure uniquely determines an m -tree. The first phase corresponds to the levels 1 through m while the second phase corresponds to levels $m+1$ through $n-1$. The two phases of the enumeration tree construction are now given.

Phase 1. At level 0, construct $n-m$ new nodes by fixing arcs $(n, 1), (n, 2), \dots, (n, n-m)$. For the node with fixed arc (n, j) , construct $n-m+1-j$ new nodes by fixing arcs $(n, j+1), \dots, (n, n-m+1)$. For any node at level l ($< m$) having arcs $(n, j_1), \dots, (n, j_l)$ fixed where $j_{k+1} > j_k$, construct $n-m+l-j_l$ new nodes by fixing $(n, j_l+1), \dots, (n, n-m-l)$.

Phase 2. At level $l \geq n$, for any partial solution having l arcs fixed, there are $n-1-l$ nodes which have no fixed arc into them. Choose one of these nodes, say q . Then $n-l+m-2$ new nodes are constructed by fixing the appropriate arcs whose 'to' node is q . In developing the enumeration tree, the node (city) selected to create the new nodes is the one whose component in the subgradient differs from 0 the most.

A partial enumeration tree for six cities and two salesmen is illustrated in Fig. 2.

3.4. Problem selection

Following the notational conventions of Geoffrion and Marsten [9], we represent the enumeration tree by a set of candidate problems which are maintained in the candidate list. Let CP_i denote a candidate problem with fixed arcs $(i_1, j_1), \dots, (i_l, j_l)$. Define Y_i corresponding to CP_i as $Y_i = \{(x_{11}, \dots, x_{nn}) : x_{i_1 j_1} = \dots = x_{i_l j_l} = 1\}$. Then CP_i is the problem.

$$\begin{aligned} \min \sum_{i,j} c_{ij} x_{ij}, \\ \sum_k x_{ij} = \begin{cases} 1, & \text{for } j=1, \dots, n-1, \\ m, & \text{for } j=n, \end{cases} \end{aligned}$$

Fig. 2. Partial enumeration tree for $n=6, m=2$.

$$\sum_k x_{ik} = \begin{cases} 1, & \text{for } i=1, \dots, n-1, \\ m, & \text{for } i=n, \end{cases}$$

$$x \in X \cap Y_i.$$

We make use of two relaxations of CP_i in the branch-and-bound algorithm. The relaxation \overline{CP}_i^1 is the Lagrangean dual,

$$\max \Theta(u, v) \quad \text{where} \quad \Theta(u, v) = \min_{x \in X \cap Y_i} \left\{ \sum_{i,j} \bar{c}_{ij} x_{ij} \right\} - \alpha,$$

while \overline{CP}_i^2 is simply

$$\Theta(\bar{u}, \bar{v}) = \min_{x \in X \cap Y_i} \left\{ \sum_{i,j} \bar{c}_{ij} x_{ij} \right\} - \alpha.$$

\overline{CP}_i^1 is used only at the initial node in the enumeration tree, and \overline{CP}_i^2 is used at all other nodes where (\bar{u}, \bar{v}) is the optimal solution of \overline{CP}_i^1 .

Let $v(\overline{CP}_i^2)$ denote the optimal objective value of \overline{CP}_i^2 . Then a lower bound for all nodes constructed from CP_i is $v(\overline{CP}_i^2)$. Let CP_{i+1} be any descendent of CP_i with $l+1$ fixed arcs and let the arcs selected by the greedy algorithm for \overline{CP}_i^2 and \overline{CP}_{i+1}^2

be given by $(i_1, j_1) \cdots (i_l, j_l)(\bar{i}_{l+1}, \bar{j}_{l+1}) \cdots (\bar{i}_{n+m}, \bar{j}_{n+m})$ and $(i_1, j_1) \cdots (i_l, j_l)(\hat{i}_{l+1}, \hat{j}_{l+1}) \cdots (\hat{i}_{n+m}, \hat{j}_{n+m})$. Since the greedy algorithm was used to obtain the solution to \overline{CP}_i^2 and \overline{CP}_{i+1}^2 , then

$$\bar{c}_{i_k j_k} \geq \bar{c}_{\bar{i}_{k-1} \bar{j}_{k-1}} \quad \text{for } k = l+2, \dots, n+m. \quad (16)$$

Thus, summing (16) we obtain

$$\sum_{k=l+2} \bar{c}_{i_k j_k} \geq \sum_{k=l+2} \bar{c}_{\bar{i}_{k-1} \bar{j}_{k-1}}. \quad (17)$$

Adding $\sum_{k=1}^l \bar{c}_{i_k j_k} + \bar{c}_{\bar{i}_{m+n} \bar{j}_{m+n}} + \bar{c}_{\hat{i}_{l+1} \hat{j}_{l+1}}$ to both sides of (17), we obtain

$$v(\overline{CP}_{i+1}^2) \geq v(\overline{CP}_i^2) + \bar{c}_{\hat{i}_{l+1} \hat{j}_{l+1}} - \bar{c}_{\bar{i}_{m+n} \bar{j}_{m+n}}. \quad (18)$$

Then the right-hand-side of (18) provides a lower bound for \overline{CP}_{i+1} . The candidate problem selected at each iteration is the one with smallest lower bound.

3.5. The algorithm

Using the ideas of the previous sections, we now summarize the new branch-and-bound algorithm for the asymmetric m -travelling salesmen problem. The algorithm incorporates a new idea which we call *staged optimization*. Following the conventions of [9], let CL denote the candidate list and INC denote the objective value of the incumbent. Let \hat{Z}^* denote an estimate of the value of the optimal solution. This estimate is based on the observed duality gap and, of course, may be either larger or smaller than the optimal value. The branch-and-bound algorithm is executed with \hat{Z}^* playing the usual role of the incumbent, INC. This may substantially aid the fathoming routine with the risk of fathoming an optimum. If a feasible solution is found such that $\text{INC} \leq \hat{Z}^*$, then the fathoming strategy using \hat{Z}^* was justified and the algorithm guarantees optimality. If the complete tree is fathomed without obtaining a feasible solution, then the fathoming strategy was not justified and the optimum has objective value greater than \hat{Z}^* . For this case \hat{Z}^* is increased and the procedure is repeated. A similar idea has been reported by Marsten and Morin [17].

The algorithm incorporating staged optimization follows:

ALG-3: Branch-and-bound method for the asymmetric m -travelling salesmen problem

0. Initialization

Choose the duality gap estimates, $\partial_1, \partial_2, \partial_3, \dots$ for staged optimization, set $t \leftarrow \infty$.

1. Solve Dual

Use ALG-1 to solve the dual. Let (u^*, v^*) denote the optimal dual variables and let x^* solve $\min_{x \in X} \{ \sum_{i,j} \bar{c}_{ij} x_{ij} \}$. Set the lower bound $L \leftarrow \Theta(u^*, v^*)$ and let (r^*, s^*) denote the subgradient of $\Theta(u^*, v^*)$.

2. Test for Duality Gap

If $r^* = s^* = 0$, stop there is no duality gap and x^* solves the primal; otherwise, set $\hat{Z}^* \leftarrow L(1 + \partial_t)$.

3. Construct First Level in Enumeration Tree

Construct the first $n - m$ nodes in the enumeration tree and place them in the candidate list.

4. Solve New Candidate Problem

Let $Y \in CL$ and let x^Y solve $\min_{x \in X \cap Y} \{ \sum_{i,j} \bar{c}_{ij} x_{ij} \}$. Let $\Theta_Y = \sum_{i,j} \bar{c}_{ij} x_{ij}^Y$, and (r_Y, s_Y) denote the subgradient.

5. Fathom Test

If $\Theta_Y > \hat{Z}^*$ go to 7.

6. Feasibility Test

If $r_Y = s_Y = 0$, $x^* \leftarrow x^Y$, $INC \leftarrow \Theta_Y$, $\hat{Z}^* \leftarrow \Theta_Y$, fathom candidate problems with lower bounds greater than Θ_Y ; otherwise go to 9.

7. Termination Test

If the candidate list is not empty, then go to 4.

8. New Stage Required?

If $INC \neq \hat{Z}^*$, then set $t \leftarrow t + 1$, $L \leftarrow \hat{Z}^*$, and go to 3; otherwise, stop with x^* as the optimum.

9. Separate

Separate Y , update the candidate list, and go to 4.

Note that ALG-3 can be easily converted into a method to find approximate solutions. The interval of uncertainty at any point in the procedure is $[INC, L]$. An additional test in Step 6 is required to make this conversion.

4. Computational experience

The branch-and-bound procedure, ALG-3, has been coded in standard FORTRAN for an in-core implementation. The code was initially tested on randomly generated asymmetric problems on a CDC 6600. The random number generator employed for the generation of problems is the one available on the CDC FTN compiler. The range used for generating the distances was $[100, 3400]$. The same range was used by Bazaraa and Goode in their computational work on the travelling salesman problem [3]. Since the code is designed for an in-core implementation, one of the major problems encountered in the computational testing was core storage. The size of the candidate list grows rapidly for the larger problems, $n > 50$, and the storage requirement soon exceeds the available 200K octal words, even with most of the data packed.

The computational efficiency of the code is sensitive to the selection of parameters. Bazaraa and Goode observed that there is a trade-off in the amount of computational effort expended in the maximization of the dual and the branch-and-bound procedure. The more time spent in ALG-1, the better the lower bound obtained. We employed $\lambda_i = 2^{-i}$ in the code and \bar{G} and \bar{H} were selected based on the size of the problem. The subgradient procedure increases the lower bound L rapidly

in the initial iterations, and minimal increases are obtained for $\bar{G} > 10$. However, for larger problems, we found it beneficial to use a larger value for \bar{G} , even though the relative increase in the lower bound is minimal. If they are chosen too large, then the candidate list grows rapidly, while if they are too small, the number of candidate problems solved increases.

Our initial computational experience centered on evaluating the behavior of the code to parameter selection and to the type of problem being solved. Table 1 summarizes computational results for asymmetric problems for $n=30, 40, 50$, and 60 with $1 \leq m \leq n/10$. The parameter settings for the first seven sets used were $\bar{H}=5$, $\bar{G}=10$ and $\partial_1=0.01$, $\partial_2=0.02$, and $\partial_3=0.03$. We found that the duality gaps for problems with $n=50$ and 60 were smaller than 0.005 and further, the number of subproblems generated with lower bounds within one percent of the solution for the Lagrangean dual was large. Problem sets 9–12 were solved with the duality gap estimates set to $\partial_1=0.005$, $\partial_2=0.01$, $\partial_3=0.015$.

The general conclusion which may be drawn from the results of problem sets 1–12 is that the duality gap seems to decrease as m increases. Further, the problems with larger values of m are easier to solve than those with smaller values of m . However, as the problem size increases, the number of candidate problems within small

Table 1.

Summary of computational results for the asymmetric m -travelling salesman problem. Each problem set contains 10 problems and all timings are in CPU seconds on a CDC 6600.

| Problem set | n | m | Solution time for ALG-1 | Number of subproblems | Duality gap | Solution time | Average solution time |

^a Results are for suboptimal solutions. (Interval of uncertainty = duality gap)

^b Some problems in the set were not solved due to storage and time limits (for set 9, 1; for set 13, 2; for set 15, 1).

percentages of the lower bound obtained from the Lagrangean dual increases. To circumvent the consequential storage problem, we have devised an approximation technique which simply consists of terminating the branch-and-bound procedure as soon as a solution is obtained. The solution so obtained is provable to be within a small percentage of the optimal solution. Since the staged optimization technique makes use of estimates of the duality gap of a problem, it is possible to obtain a suboptimal solution within a known percentage of the true solution by terminating the branch-and-bound procedure as soon as an m -tour is obtained. This approximate solution technique was tested on problems for $n = 60$. The results are summarized in problem sets 13–18 of Table 1. To obtain a tighter lower bound, $\bar{G} = 12$ was used with $\partial_1 = 0.005$, $\partial_2 = 0.01$, and $\partial_3 = 0.02$.

Table 2 reports computational results for the solution of 25 100-city problems for which solutions were obtained. There were 25 other problems which terminated due

to storage limitations before locating an m -tour. For the use of the approximate technique, a better selection procedure, which makes use of the subgradient, can be devised so that an m -tour can be located before the number of candidate problems becomes unmanageable (see [1]).

To gain insight into the solution of symmetric m -travelling salesmen problems, we attempted to solve 50 100-city problems by randomly generating such problems. The range on the costs used was the same as for asymmetric problems. For such problems, the code was slightly modified so that the subgradient employed had n rather than $2n$ components. However, the enumeration tree was not modified for these problems, nor were other specializations made. Hence, the same solution may be enumerated twice in the branch-and-bound tree. Computational results for 15 problems which were successfully solved are given in Table 3. The remaining 35 were terminated due to storage limits. The problems which were solved had negligible duality gaps, and thus, solutions were obtained before the candidate list grew. The computational results indicate that the duality gap for large problems is exceedingly small. Thus, even though minimal increases are obtained in the course of final iterations of the subgradient procedure for maximizing the dual, it is beneficial to employ larger values for \bar{G} .

Table 4 gives results on Euclidean problems obtained by the use of intercity distances which were provided by the Civil Aeronautics Board for 59 cities. Because the code has not been designed for the solution of such problems specifically, the computational experience on these problems is not extensive. Rather, the focus here

Parameters: $\bar{H} = 5$, $\bar{G} = 20$, $\partial_1 = 0.005$, $\partial_2 = 0.01$, $\partial_3 = 0.015$.^a $\partial_1 = 0.01$

was to obtain insight into the nature of solutions to such problems. Five networks were chosen arbitrarily and three problems were defined for each network. The first four networks have 30 nodes each. Networks III and IV differ only in the choice of the base node. The most interesting inference that may be drawn from the solutions is the relationship between the duality gaps for the problems and the solutions. The larger the duality gap, the harder the problem. Furthermore, note the manner in which solutions to problems on the same network are related. From the solutions to the problems illustrated in Figs. 3 and 4, it would seem that realistic m -travelling salesmen problems would have to be further constrained to ensure that each salesman visit at least some minimum number of cities. Failing this constraint, solutions of the kind illustrated, where some salesmen travel to only one other city, may be expected. For the problems on networks III, IV, and V, even though the initial estimates of the upper bounds used were quite close to the true duality gap, the number of subproblems examined before verification of optimality is large.

Based on our computational experience using the algorithm developed in this exposition, we have arrived at the following conclusions:

- (i) The duality gap for problems with up to 100 cities is quite small (less than 1%).
- (ii) Exact solutions for problems with up to 50 cities can be obtained routinely with the implementation of the algorithm reported.
- (iii) A in-core/out-of-core algorithm using this technique could be used to solve problems having 100 cities.
